## Qulcek E <br> DEFINITIONS <br> $\lrcorner$ STATISTICS－A set of tools for collecting， organizing，presenting，and analyzing numerical facts or observations． <br> Descriptive Statistics－procedures used to organize and present data in a convenient， useable，and communicable form． <br> ．Inferential Statistics－procedures employed to arrive at broader generalizations or inferences from sample data to populations． <br> －STATISTIC－A number describing a sample characteristic．Results from the manipulation of sample data according to certain specified procedures． <br> $\perp$ DATA－Characteristics or numbers that are collected by observation． <br> $\perp$ POPULATION－A complete set of actual or potential observations． <br> 」 PARAMETER－A number describing a population characteristic；typically，inferred from sample statistic． <br> 〕 SAMPLE－A subset of the population selected according to some scheme． <br> －RANDOM SAMPLE－A subset selected in such a way that each member of the population has an equal opportunity to be selected．Ex．lottery numbers in a fair lottery <br> 〕 VARIABLE－A phenomenon that may take on different values．

 STATISTICS
## THE BASIC PRINCIPLES OF STATISTICS FOR INTRODUCTORY COURSES

コ MEAN－The point in a distribution of measurements about which the summed deviations are equal to zero． Average value of a sample or population． POPULATION MEAN SAMPLE MEAN

$$
\mu=\frac{1}{N} \sum_{i=1}^{N} x_{i} \quad \bar{x}=\frac{1}{n} \sum_{i=1}^{n} x_{i}
$$

Note：The mean is very sensitive to extreme measure－ ments that are not balanced on both sides．
コ WEIGHTED MEAN－Sum of a set of observations multiplied by their respective weights．divided by the sum of the weights：

## WEIGHTED MEAN

where $\boldsymbol{w}_{i}=$ weight； $\boldsymbol{x}_{i}=$ observation； $\boldsymbol{G}=$ number of observation groups．Calculated from a population， sample，or groupings in a frequency distribution．
Ex．In the FrequencyDistribution below，the mean is 80．3；calculated by using frequencies for the $w_{i}$＇s． When grouped，use class midpoints for $x_{i}$＇s．
－MEDIAN－Observation or potential observation in a set that divides the set so that the same number of observations lie on each side of it．For an odd number of values，it is the middle value；for an even number it is the average of the middle two．
Ex．In the Frequency Distribution table below，the median is 79.5 ．
コ MODE－Observation that occurs with the greatest frequency．Ex．In the Frequency Distribution table below，the mode is 88.

## MEASURES OF DISPARSION

$\square$ SUM OF SQUARES（SS）－Deviations from the mean，squared and summed：
PopulationSS $=\Sigma\left(x_{i}-\mu_{x}\right)^{2}$ or $\sum x_{i}^{2}-\frac{\left(\sum x_{i}\right)^{2}}{N}$
Sample SS $=\sum\left(x_{i}-\bar{x}\right)^{2}$ or $\sum x_{i}{ }^{2}-\frac{\left(\sum x_{i}\right)^{2}}{n}$
$\square$ VARIANCE－The average of square differ－ ences between observations and their mean．
population variance sample variance $\sigma^{2}=\frac{1}{N} \sum_{i=1}^{N}\left(x_{i}-\mu\right)^{2} \quad \mathrm{~s}^{2}=\frac{1}{n-1} \sum_{i=1}^{n}\left(\mathrm{x}_{i}-\overline{\mathrm{x}}\right)^{2}$

## VARIANCES FOR GROUPED DATA

POPULATION
SAMPLE
$\sigma^{2}=\frac{1}{N} \sum_{i=1}^{G} f_{i}\left(m_{i}-\mu\right)^{2} \quad s^{2}=\frac{1}{n-1} \sum_{i=1}^{G} f_{i}\left(m_{i}-\bar{x}\right)^{2}$
－STANDARD DEVIATION－Square root of Ex．Pop．S．D．$\quad \sigma=\sqrt{\frac{1}{N} \sum_{i=1}^{N}\left(x_{i}-\mu\right)^{2}}$

## GRAPHING TECANIOUS

| CLASS | $f$ | Cum f | $\%$ |
| :---: | :---: | :---: | :---: |
| $65-67$ | 3 | 3 | 4.84 |
| $68-70$ | 8 | 11 | 17.74 |
| $71-73$ | 5 | 16 | 25.81 |
| $74-76$ | 9 | 25 | 40.32 |
| $77-79$ | 6 | 31 | 50.00 |
| $80-82$ | 4 | 35 | 56.45 |
| $83-85$ | 8 | 43 | 69.35 |
| $86-88$ | 8 | 51 | 82.26 |
| $89-91$ | 6 | 57 | 91.94 |
| $92-94$ | 1 | 58 | 93.55 |
| $95-97$ | 2 | 60 | 96.77 |
| $98-100$ | 2 | 62 | 100.00 |

－BAR GRAPH－A form of graph that uses bars to indicate the frequency of occurrence of observations．
－Histogram－a form of bar graph used with interval or ratio－scaled variables．
－Interval Scale－a quantitative scale that permits the use of arithmetic operations．The zero point in the scale is arbitrary．
－Ratio Scale－same as interval scale except that there is a true zero point．
$\square$ FREQUENCY CURVE－A form of graph representing a frequency distribution in the form of a continuous line that traces a histogram． －Cumulative Frequency Curve－a continuous line that traces a histogram where bars in all the lower classes are stacked up in the adjacent higher class．It cannot have a negative slope．
－Normal curve－bell－shaped curve．
－Skewed curve－departs from symmetry and tails－off at one end．

## GROUPING OF DATA

## CUMULATIVE FREQUENG／PARGENTAGE DISTRIEUTIONS

## －CUMULATIVE FREQUENCY DISTRI－

 BUTION－A distribution which shows the to－ tal frequency through the upper real limit of each class．－CUMULATIVE PERCENTAGE DISTRI－
BUTION－A distribution which shows the to－ tal percentage through the upper real limit of each class．

CUMULATIVE FREQUENCY／PERCENTAGE DISTRIBUTION

GROUPED FREQUENCY DISTRIBUTION
A frequency distribution in which the values of the variable have been grouped into classes．

GROUPED
FREQUENCY DISTRIBUTION

| CLASS | $\boldsymbol{f}$ | CLASS | $f$ |
| :---: | :---: | :---: | :---: |
| $98-100$ | 2 | $80-82$ | 4 |
| $95-97$ | 2 | $77-79$ | 6 |
| $92-94$ | 1 | $74-76$ | 9 |
| $89-91$ | 6 | $71-73$ | 5 |
| $86-88$ | 8 | $68-70$ | 8 |
| $83-85$ | 8 | $65-67$ | 3 |

Probability of occurrence $\rho(A)=$ Number of outcomes favoring Event $A$ of Event $A$

Total number of outcomes

- SAMPLE SPACE - All possible outcomes of an experiment.
TYPE OF EVENTS
- Exhaustive - two or more events are said to be exhaustive if all possible outcomes are considered. Symbolically, $\rho(\mathrm{A}$ or B or... $)=1$.
- Non-Exhaustive -two or more events are said to be nonexhaustive if they do not exhaust all possible outcomes. - Mutually Exclusive - Events that cannot occur simultaneously: $\rho(\mathrm{A}$ and B$)=0$; and $\rho(\mathrm{A}$ or B$)=\rho(\mathrm{A})+\rho(\mathrm{B})$. Ex. males, females
- Non-Mutually Exclusive - Events that can occur simultaneously: $\rho(\mathrm{A}$ or B$)=\rho(\mathrm{A})+\rho(\mathrm{B})-\rho(\mathrm{A}$ and B$)$. Ex. males, brown eyes.
-Independent - Events whose probability is unaffected by occurrence or nonoccurrence of each other: $\rho(\mathrm{A} \mid \mathrm{B})=$ $\rho(\mathrm{A}) ; \rho(\mathrm{B} \mid \mathrm{A})=\rho(\mathrm{B}) ;$ and $\rho(\mathrm{A}$ and B$)=\rho(\mathrm{A}) \rho(\mathrm{B})$ Ex. gender and eye color
-Dependent - Events whose probability changes depending upon the occurrence or non-occurrence of each other: $\rho(\mathrm{A} \mid \mathrm{B})$ differs from $\rho(\mathrm{A}) ; \rho(\mathrm{B} \mid \mathrm{A})$ differs from $\rho(\mathrm{B})$; and $\rho(\mathrm{A}$ and B$)=\rho(\mathrm{A}) \rho(\mathrm{B} \mid \mathrm{A})=\rho(\mathrm{B}) \rho(\mathrm{A} \mid \mathrm{B})$ Ex. race and eye color.
JOINT PROBABILITIES - Probability that 2 or more events occur simultaneously.
- MARGINAL PROBABILITIES or Unconditional Probabilities = summation of probabilities.
$\square$ CONDITIONAL PROBABILITIES - Probability of $A$ given the existence of $S$, written, $\rho(A \mid S)$.
$\square$ EXAMPLE-Given the numbers 1 to 9 as observations in a sample space: -Events mutually exclusive and exhaustiveExample: $\rho$ (all odd numbers); $\rho$ ( all even numbers) -Events mutually exclusive but not exhaustiveExample: $\rho$ (an even number); $\rho$ (the numbers 7 and 5) -Events neither mutually exclusive or exhaustiveExample: $\rho$ (an even number or a 2)

SAMPLING DISTRIBUTION - A theoretical probability distribution of a statistic that would result from drawing all possible samples of a given size from some population.

## THE STANDARD ERROR OF THE MEAN

A theoretical standard deviation of sample mean of a given sample size, drawn from some specified population.
DWhen based on a very large, known population, the standard error is:

$$
\sigma_{\bar{x}}=\frac{\sigma}{\sqrt{n}}
$$

When estimated from a sample drawn from very large population, the standard error is:

$$
\sigma_{\bar{x}} \approx \frac{s}{\sqrt{\mathbf{n}}}
$$

A mapping or function that assigns one and only one numerical value to each outcome in an experiment.

- DISCRETE RANDOM VARIABLES - Involves rules or probability models for assigning or generating only distinct values (not fractional measurements).
- BINOMIAL DISTRIBUTION - A model for the sum of a series of $\mathbf{n}$ independent trials where trial results in a 0 (failure) or 1 (success). Ex. Coin toss $p(s)=\binom{n}{s} \pi^{s}(1-\pi)^{n-s}$
where $\mathbf{p}(\mathbf{s})$ is the probability of $\mathbf{s}$ success in $\mathbf{n}$ trials with a constant $\pi$ probability per trials, and where $\binom{\boldsymbol{n}}{\boldsymbol{s}}=\frac{n!}{\boldsymbol{s !} \boldsymbol{n}-\boldsymbol{s})!}$ Binomial mean: $\mu=n \pi$

Binomial variance: $\sigma^{2}=n \pi(1-\pi)$
As $n$ increases, the Binomial approaches the Normal distribution.

- HYPERGEOMETRIC DISTRIBUTION A model for the sum of a series of $\mathbf{n}$ trials where each trial results in a 0 or 1 and is drawn from a small population with $\mathbf{N}$ elements split between $\mathbf{N}_{1}$ successes and $\mathbf{N}_{2}$ failures. Then the probability of splitting the $\mathbf{n}$ trials between $\mathbf{x}_{\mathbf{1}}$ successes and $\mathbf{x}_{\mathbf{2}}$ failures is:
$p\left(x_{1}\right.$ and $\left.x_{2}\right)=\frac{\frac{x_{1}!\left(N_{1}-x_{1}\right)!}{x_{2}!\left(N_{2}-x_{2}\right)!}}{\frac{N!}{n!(N)!}}$ $n!(N-n)!$
Hypergeometric mean: $\mu_{1}=\boldsymbol{E}\left(\boldsymbol{x}_{1}\right)=\frac{n N_{1}}{N}$ and variance:

$$
\sigma^{2}=\frac{N-n}{N-1}\left[\frac{n N_{1}}{N}\right]\left[\frac{N_{2}}{N}\right]
$$

$\square$ POISSON DISTRIBUTION - A model for the number of occurrences of an event $\boldsymbol{x}=$ $0,1,2, \ldots$, when the probability of occurrence is small, but the number of opportunities for the occurrence is large, for $\mathbf{x}=\mathbf{0}, \mathbf{1}, 2,3 \ldots$ and $\boldsymbol{\lambda}>\mathbf{0}$, otherwise $\boldsymbol{P}(\boldsymbol{x})=\mathbf{0}$.

Poisson mean and variance: $\lambda$

For continuous variables, frequencies are expressed in terms of areas under a curve

- CONTINUOUS RANDOM VARIABLES - Variable that may take on any value along an uninterrupted interval of a numberline.
NORMAL DISTRIBUTION - bell curve; a distribution whose values cluster symmetrically around the mean (also median and mode).

$$
f(x)=\frac{1}{\sigma \sqrt{2 \pi}} e^{-(x-\mu)^{2} / 2 \sigma^{2}}
$$

where $f(x)=$ frequency at a given value
$\sigma=$ standard deviation of the
distribution
= approximately 3.1416
= approximately 2.7183
$\mu=$ the mean of the distribution
$\boldsymbol{x}=$ any score in the distribution

- STANDARD NORMAL DISTRIBUTION - A normal random variable $Z$, that has a mean of 0 , and standard deviation of 1 .
D Z-VALUES - The number of standard deviations a specific observation lies from the mean:

## TESTING STATISTICAL HPootheses

- LEVEL OF SIGNIFICANCE - A probability value considered rare in the sampling distribution. specified under the null hypothesis where one is willing to acknowledge the operation of chance factors. Common significance levels are $1 \%$, $5 \%, 10 \%$. Alpha $(\alpha)$ level $=$ the lowest leve for which the null hypothesis can be rejected Thesignificance level determinesthe critical region.
- NULL HYPOTHESIS $\left(H_{0}\right)$ - A statement that specifies hypothesized value(s) for one or more of the population parameter. [Ex. $\boldsymbol{H}_{\boldsymbol{\theta}}=\mathrm{a}$ coin is unbiased. That is $\boldsymbol{p}=0.5$.]
- ALTERNATIVE HYPOTHESIS $\left(H_{I}\right)$ - A statement that specifies that the population parameter is some value other than the one specified under the null hypothesis. [Ex. $\boldsymbol{H}_{\boldsymbol{I}}=$ a coin is biased. That is $\boldsymbol{p} \neq 0.5$. 1

1. NONDIRECTIONAL HYPOTHESIS an alternative hypothesis $\left(\boldsymbol{H}_{l}\right)$ that states only that the population parameter is different from the one specified under $\boldsymbol{H}_{0}$. Ex. $\boldsymbol{H}_{\mathbf{1}}: \boldsymbol{\mu} \neq \boldsymbol{\mu}_{\boldsymbol{0}}$ Two-Tailed Probability Value is employed when the alternative hypothesis is non-directional.
2. DIRECTIONAL HYPOTHESIS - a alternative hypothesis that states the direction in which the population parameter differs from the one specified under $\boldsymbol{H}_{\boldsymbol{0}}$. Ex. $\boldsymbol{H}_{1} ; \boldsymbol{\mu}>\boldsymbol{\mu}_{\boldsymbol{\theta}}$ or $\boldsymbol{H}_{\mathbf{1}}: \boldsymbol{\mu}<\boldsymbol{\mu}_{\boldsymbol{p}}$ One-Tailed Probability Value is employed when the alternative hypothesis is directional.

- NOTION OF INDIRECT PROOF - Strict interpretation of hypothesis testing reveals that the' null hypothesis can never be proved. [Ex. If we tos: a coin 200 times and tails comes up 100 times. it is no guarantee that heads will come up exactly half the time in the long rum; small discrepancies might exist. A bias can exist even at a small magnitude. We can make the assertion however that NO BASIS EXISTS FOR REJECTING THE HYPOTHESIS THAT THE COIN IS UNBIASED. (The null hypothesis is not rejected) When employing the 0.05 level of significand reject the null hypothesis when a given resu occurs by chance $5 \%$ of the time or less.]

## - TWO TYPES OF ERRORS

-Type 1 Error (Type $\alpha$ Error) = the rejection of $\vec{H}_{0}$ when it is actually true. The probability of a type 1 error is given by $\alpha$.
-Type II Error (Type $\beta$ Error) $=$ The acceptance of $\boldsymbol{H}_{0}$ when it is actually false. The probability of a type II error is given by $\beta$.

## Statistical <br> Hypotheses

Decision:

## CENTRAL LIMT THEOREM

## (for sample mean $\bar{x}$ )

-If $x_{1}, x_{2}, x_{3}, \ldots x_{n}$, is a simple random sample of $n$ elements from a large (infinite) population, with mean $\mathrm{mu}(\mu)$ and standard deviation $\sigma$, then the distribution of $\overline{\mathrm{x}}$ takes on the bell shaped distribution of a normal random variable as n increases and the distribution of the ratio:

## $\frac{\bar{x}-\mu}{\sigma / \sqrt{n}}$

approaches the standard normal distribution as $n$ goes to infinity. In practice, a normal approximation is acceptable for samples of 30 or larger.

NBIASEDNESS - Property of a reliable esrmator being estimated.

- Unbiased Estimate of a Parameter - an estimate that equals on the average the value of the parameter.
Ex. the sample mean is an unbiased estimator of the population mean.
- Biased Estimate of a Parameter - an estimate that does not equal on the average the value of the parameter.
Ex. the sample variance calculated with $n$ is a biased estimator of the population variance, however, when calculated with $n$-1 it is unbiased.
$\lrcorner$ STANDARD ERROR - The standard deviation of the estimator is called the standard error. Ex. The standard error for $\overline{\mathrm{x}}$ 's is. $\sigma_{\overline{\mathrm{x}}}=\sigma / \sqrt{\mathrm{n}}$ This has to be distinguished from the STANDARD DEVIATION OF THE SAMPLE:

$$
s=\sqrt{\left(\frac{1}{n-1}\right) \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}}
$$

- The standard error measures the variability in the $\overline{\mathrm{x}}$ 's around their expected value $\mathrm{E}(\overline{\mathrm{x}})$ while the standard deviation of the sample reflects the variability in the sample around the sample's mean ( $\overline{\mathrm{x}}$ ).

د USED WHEN THE STANDARD DEVIATION IS UNKNOWN -Use of Student's $t$. When $\sigma$ is not known, its value is estimated from sample data.

- $t$-ratio- the ratio employed in the testing of ypotheses or determining the significance of a difference between means (two-sample case) involving a sample with a t -distribution. The formula is:
$\overline{\mathrm{x}}-\boldsymbol{\mu}$ where $\mu=$ population mean under $\boldsymbol{H}_{\boldsymbol{0}}$

## and

-Distribution-symmetrical distribution with a mean of zero and standard deviation that approaches one as degrees of freedom increases (1.e.. approaches the Z distribution).

Assumption and condition required in assuming $t$-distribution: Samples are drawn from a normally distributed population and $\sigma$ ( population standard deviation) is unknown.

- Homogeneity of Variance- If 2 samples are being compared, the assumption in using $t$-ratio 1s that the variances of the populations from where the samples are drawn are equal.
- Estimated $\sigma_{\bar{X}_{1}}-\overline{X_{2}}$ (that is $s_{\overline{X_{1}}}-\overline{X_{2}}$ ) is based on the unbiased estimate of the population variance.
- Degrees of Freedom $(d f)$-the number of values that are free to vary after placing certain restrictions on the data.
Example. The sample (43,74,42,65) has $n=4$. The sum is 224 and mean $=56$. Using these 4 numbers and determining deviations from the mean, we'll have $\ddagger$ deviations namely $(-13,18,-14,9)$ which sum up to zero. Deviations from the mean is one restriction we have imposed and the natural consequence is that the sum of these deviations should equal zero. For this to happen, we can choose any number but our freedom to choose is limited to only 3 numbers because one is restricted by the requirement that the sum of the deviations should equal zero. We use the equality:

$$
\left(x_{1}-\bar{x}\right)+\left(x_{2}-\bar{x}\right)+\left(x_{3}-\bar{x}\right)+\left(x_{f}-\bar{x}\right)=0
$$

So given a mean of 56, if the first 3 observations are 43, 74, and 42, the last observation has to be 65. This single restriction in this case helps us determine df. The formula is $n$ less number of restrictions. In this case, it is $n-l=4-1=3 d f$.

- $t$-Ratio is a robust test- This means that statistical inferences are likely valid despite fairly large departures from normality in the population distribution. If normality of population distribution is in doubt, it is wise to increase the sample size.

## USING THE Z. STATISTIC

- USED WHEN THE STANDARD DEVIATION IS KNOWN: When $\sigma$ is known it is possible to describe the form of the distribution of the sample mean as a $Z$ statistic. The sample must be drawn from a normal distribution or have a sample size ( n ) of at least 30 .
$z=\frac{\bar{x}-\mu}{\sigma_{\tilde{x}}} \quad$ where $\mathrm{u}=$ population mean (either

- Critical Region - the portion of the area under the curve which includes those values of a statistic that lead to the rejection of the null hypothesis.

The most often used significance levels are $0.01,0.05$, and 0.1 . For a one-tailed test using $z$ statistic, these correspond to $z$-values of 2.33 , 1.65 , and 1.28 respectively. For a two-tailed test, the critical region of 0.01 is split into two equal outer areas marked by $z$-values of $|2.58|$.
Example 1. Given a population with $\mu=250$ and $\sigma=50$, what is the probability of drawing a sample of $n=100$ values whose mean ( $x$ ) is at least 255? In this case, $Z=1.00$. Looking at Table $A$, the given area for $Z=1.00$ is 0.3413 . To its right is 0.1587( $=0.5-0.3413$ ) or $15.85 \%$.
Conclusion: there are approximately 16 chances in 100 of obtaining a sample mean $=$ 255 from this population when $n=100$.
Example 2. Assume we do not know the population mean. However, we suspect that it may have been selected from a population with $\mu=250$ and $\sigma=50$, but we are not sure. The hypothesis to be tested is whether the sample mean was selected from this population. Assume we obtained from a sample ( $n$ ) of 100, a sample mean of 263. Is it reasonable to assume that this sample was drawn from the suspected population?

1. $\boldsymbol{H}_{\boldsymbol{0}}: \mu=250$ (that the actual mean of the population from which the sample is drawn is equal to 250) $\boldsymbol{H}_{1}: \mu$ not equal to 250 (the alternative hypothesis is that it is greater than or less than 250 , thus a two-tailed test).
2. $z$-statistic will be used because the population $\sigma$ is known.
3. Assume the significance level $(\alpha)$ to be 0.01 . Looking at Table A, we find that the area beyond azof 2.58 is approximately 0.005 .
To reject $\boldsymbol{H}_{\boldsymbol{g}}$ at the 0.01 level of significance, the absolute value of the obtained $z$ must be equal to or greater than $\left|z_{0.01}\right|$ or 2.58 . Here the value of $z$ corresponding to sample mean $=263$ is 2.60 .

- CONCLUSION-Since this obtained $z$ falls within the critical region, we may reject $\boldsymbol{H}_{\boldsymbol{o}}$ at the 0.01 level of significance.
- CONFIDENCE INTERVAL- Interval within which we may consider a hypothesis tenable. Common confidence intervals are $90 \%, 95 \%$, and $99 \%$. Confidence Limits: limits defining the confidence interval.
(1- $\alpha$ ) $100 \%$ confidence interval for $\mu$

$$
\begin{aligned}
& 100 \% \text { contidence interval for } \mu: \\
& \overline{\mathrm{x}}_{\mathrm{i}}-\mathrm{z}_{\alpha 2}(\sigma / \sqrt{\mathrm{n}}) \leq \mu \leq \overline{\mathrm{x}}+\mathrm{z}_{\alpha 2}(\sigma / \sqrt{\mathrm{n}})
\end{aligned}
$$

where $Z_{\alpha / 2}$ is the value of the standard normal variable $\mathrm{z}^{\alpha / 2}$ that puts $\alpha / 2$ percent in each tail of the distribution. The confidence interval is the complement of the critical regions.
A $t$-statistic may be used in place of the $z$-statistic when $\sigma$ is unknown and $s$ must be used as an estimate. (But note the caution in that section.)

Example. Given $\overline{\mathrm{x}}=108, \mathrm{~s}=15$, and $\mathrm{n}=26$ estimate a $95 \%$ confidence interval for the population mean. Since the population variance is unknown, the t-distribution is used. The resulting interval, using a $t$-valve of 2.060 from Table B (row 25 of the middle column), is approximately 102 to 114. Consequently, any hypothesized $\mu$ between 102 to 114 is tenable on the basis of this sample. Any hypothesized $\mu$ below 102 or above 114 would be rejected at 0.05 significance.
COMPARISON BETWEEN $\boldsymbol{t}$ AND

## $z$ DISTRIBUTIONS

Although both distributions are symmetrical about a mean of zero, the $t$-distribution is more spread out than the normal distribution $(z$-distribution).

Thus a much larger value of $t$ is required to mark off the bounds of the critical region of rejection. As $d f$ increases, differences between $\boldsymbol{z}$ - and $\boldsymbol{t}$ - distributions are reduced. Table A $(z)$ may be used instead of Table B $(t)$ when $\mathrm{n}>30$. To use either table when $\mathrm{n}<30$, the sample must be drawn from a normal population.

# TESTINE INDEPENDENT SAMPLES 

$\square$ SAMPLING DISTRIBUTION OF THE DIFFERENCE BETWEEN MEANS- If a number of pairs of samples were taken from the same population or from two different populations, then:

- The distribution of differences between pairs of sample means tends to be normal (z-distribution).
- The mean of these differences between means $\mu_{\bar{x}_{1}-\overline{\mathrm{x}}}$ is equal to the difference between the population means, that is $\mu_{1}-\mu_{2}$.
Z-DISTRIBUTION: $\sigma_{1}$ and $\sigma_{2}$ are known
- The standard error of the difference between means $\sigma_{\bar{x}_{1}-\bar{x}_{2}}=\sqrt{\left(\sigma_{1}^{2}\right) / n_{1}+\left(\sigma_{2}^{2}\right) / n_{2}}$
- Where $\left(\mu_{1}-\mu_{2}\right)$ represents the hypothesized difference in means, the following statistic can be used for hypothesis tests:

$$
Z=\frac{\left(\bar{x}_{1}-\bar{x}_{2}\right)-\left(\mu_{1}-\mu_{2}\right)}{\sigma_{\bar{x}_{1}-\bar{x}_{2}}}
$$

- When $n_{1}$ and $n_{2}$ are $>30$, substitue $s_{1}$ and $s_{2}$ for $\sigma_{1}$ and $\sigma_{2}$, respectively.

$$
S_{\bar{x}_{1}-\bar{x}_{2}}=\sqrt{\left(\frac{S S_{1}+S S_{2}}{n_{1}+n_{2}-2}\right)\left(\frac{1}{n_{1}}+\frac{1}{n_{2}}\right)}
$$

To obtain sum of squares (SS) see Measures of Central Tendency on page 1)

- POOLED $\boldsymbol{t}$-TEST
- Distribution is normal
- $n<30$
- $\sigma_{1}$ and $\sigma_{2}$ are not known but assumed equal
- The hypothesis test may be 2 tailed ( $=$ vs. $\neq$ ) or 1 tailed: $\mu_{1} \leq \mu_{2}$ and the alternative is $\mu_{1}>\mu_{2}$ (or $\mu_{I} \geq$ $\mu_{2}$ and the alfernative is $\mu_{1}<\mu_{2}$.)
degrees of freedom $(d f):\left(n_{1}-1\right)+\left(n_{2}-1\right)=n_{1}+n_{2}-2$. - Use the given formula below for estimating $\sigma_{x_{1}-\overline{x_{2}}}$ to determine $\boldsymbol{s}_{\bar{x}_{l}-\bar{x}}$
- Determine the critical region for rejection by as signing an acceptable level of significance and look ing at the $\boldsymbol{t}$-table with $d \boldsymbol{f}=\mathbf{n}_{\mathbf{1}}+\mathbf{n}_{\mathbf{2}} \mathbf{- 2}$.
- Use the following formula for the estimated stan-

$$
\begin{aligned}
& \text { dard error: } \\
& \left.s_{x_{1}-\bar{x}_{2}}=\sqrt{\left[\frac{\left(n_{1}-1\right) s_{1}^{2}+\left(n_{2}-1\right) s_{2}^{2}}{n_{1}+n_{2}-2}\right]\left[\frac{n_{1}+n_{2}}{n_{1} n_{2}}\right]}\right]
\end{aligned}
$$

## F. TEST

D HETEROGENEITY OF VARIANCES may be determined by using the F-test:

$$
F=\frac{s_{1}^{2}(\text { larger variance })}{s_{2}^{2}(\text { smaller variance })}
$$

DULL HYPOTHESIS- Variances are equal and their ratio is one.
DALTERNATIVE HYPOTHESIS-Variances differ and their ratio is not one.

- Look at "Table C" below to determine if the variances are significantly different from each other. Use degrees of freedom from the 2 samples:( $n_{1}-1, n_{2}-1$ ).

## CORBELATED SAMPLES

- STANDARD ERROR OF THE DIFFERENCE between Means for Correlated Groups The general formula is:

$$
S_{\bar{x}_{1}-\bar{x}_{2}}=\sqrt{s_{\bar{x}_{1}}^{2}+s_{\bar{x}_{2}}^{2}-2 r s_{\bar{x}_{1}} s_{\bar{x}_{2}}}
$$

where $r$ is Pearson correlation

- By matching samples on a variable correlated with the criterion variable, the magnitude of the standard error of the difference can be reduced.
- The higher the correlation, the greater the reduction in the standard error of the difference.

## ANALYSIS OF VARIANCE (ANOVA)

$\square$ PURPOSE- Indicates possibility of overall mean effect of the experimental treatments before investigating a specific hypothesis.

- ANOVA- Consists of obtaining independent estimates from population subgroups. It allows for the partition of the sum of squares into known components of variation.

## $\square$ TYPES OF VARIANCES

- Between-Group Variance (BGV)-reflects the magnitude of the difference(s) among the group means.
- Within-Group Variance (WGV)- reflects the dispersion within each treatment group. It is also referred to as the error term.

## CALCULATING VARIANCES

- Following the F-ratio, when the BGV is large relative to the WGV, the F-ratio will also be large.

$$
B G V=\frac{n \sum\left(\hat{x}_{i}-\bar{x}_{t o t}\right)^{2}}{k-1}
$$

where $x_{i}=$ mean of $i^{\text {th }}$ treatment group and $x_{\text {tot }}$ $=$ mean of all $n$ values across all $k$ treatment groups. $W \boldsymbol{W} V=\boldsymbol{S S _ { I }}+\boldsymbol{S S _ { 2 }}+\ldots+\boldsymbol{S} \boldsymbol{S}_{\boldsymbol{k}}$ $n-k$
where the SS's are the sums of squares (see Measures of Central Tendency on page 1) of each subgroup's values around the subgroup mean.
USING F-RATIO- $\quad F=B G V / W G V$

- Degrees of freedom are $k-1$ for the numerator and $\mathrm{n}-\mathrm{k}$ for the denominator.
- If $\boldsymbol{B} \boldsymbol{G} \boldsymbol{V}>\boldsymbol{W} \boldsymbol{G} \boldsymbol{V}$, the experimental treatments are responsible for the large differences among group means. Null hypothesis: the group means are estimates of a common population mean.

## PROPORTIONS

In random samples of size $n$, the sample proportion $\boldsymbol{p}$ fluctuates around the proportion mean $=\pi$ with a proportion variance of $\frac{\pi(I-\pi)}{n}$ proportion standard error of $\sqrt{\pi(1-\pi) / n}$
As the sampling distribution of $p$ increases, it concentrates more around its target mean. It also gets closer to the normal distribution. In which case: $z=\frac{p-\pi}{\sqrt{\pi(1-\pi) / n}}$

## CORRELATION

Definition - Correlation refers to the relationship between two variables. The Correlation Coefficient is a measure that expresses the extent to which two variables are related.

- "PEARSON r"METHOD (Product-Moment Correlation Coefficient) - Corelation coefficient employed with interval- or ratio-scaled variables.
Ex.: Given observations to two variables $\boldsymbol{X}$ and $\boldsymbol{Y}$, we can compute their corresponding $z$ values: $Z_{x}=(x-\bar{x}) / s_{x}$ and $Z_{y}=(y-\bar{y}) / s_{y}$.
- The formulas for the Pearson correlation (r):

$$
r=\frac{\Sigma(x-\bar{x})(y-\bar{y})}{\sqrt{\boldsymbol{S S}} \cdot \underline{S S_{y}}}
$$

Use the above formula for large samples.
Use this formula (also known as the Mean-Deviation Method of computing the Pearson r) for small samples. $=\frac{\sum\left(z_{x} z_{y}\right)}{n}$
$\square$ RAW SCORE METHOD is quicker and can be used in place of the first formula above when the sample values are available.

$$
\mathrm{r}=\frac{\Sigma x y-\frac{(\Sigma x)(\Sigma y)}{N}}{\sqrt{\left[\Sigma x^{2}-\frac{\left(\sum x\right)^{2}}{n}\right]\left[\Sigma y^{2}-\frac{\left(\Sigma y^{2}\right)}{n}\right.}}
$$

- Most widely-used non-parametric test
-The $\chi^{2}$ mean $=$ its degrees of freedom.
- The $\chi^{2}$ variance $=$ twice its degrees of freedom
- Can be used to test one or two independent samples.
- The square of a standard normal variable is a
chi-square variable.
- Like the t-distibution, it has different distributions depending on the degrees of freedom.
D DEGREES OF FREEDOM (d.f.) COMPUTATION
- If chi-square tests for the goodness-of-fit to a hy pothesized distribution,

## d.f. $=\boldsymbol{g}-\boldsymbol{I}-\boldsymbol{m}$, where

$g=$ number of groups, or classes. in the frequencs distribution.
$\boldsymbol{m}=$ number of population parameters that must be estimated from sample statistics to test the hypothesis.

- If chi-square tests for homogeneity or contingencs:
d. $f$. $=$ (rows-1) (columns-1)

GOODNESS-OF-FIT TEST- To apply the chi-square distribution in this manner. the critical chi-square value is expressed as
$\sum \frac{\left(f_{o}-f_{e}\right)^{2}}{f_{e}}$ where
$f_{0}=$ observed frequency of the variable
$f_{\boldsymbol{e}}=$ expected frequency (based on hypothesized population distribution).

- TESTS OF CONTINGENCY- Application of Chi-square tests to two separate populations to test statistical independence of attributes.
- TESTS OF HOMOGENEITY- Application of

Chi-square tests to two samples to test if they came from populations with like distributions.

- RUNS TEST- Tests whether a sequence (to comprise a sample) is random. The following equations are applied:

$$
\begin{aligned}
& \text { ons are applied: } \\
& (\bar{R})=\frac{2 n_{1} n_{2}}{n_{1}+n_{2}}+1 \text { nnd } S_{R} \sqrt{\frac{2 n_{1} n_{2}\left(2 n_{1} n_{2}-n_{1}-n_{2}\right)}{\left(n_{1}+n_{2}\right)^{2}\left(n_{1}+n_{2}-1\right)}}
\end{aligned}
$$

Where
$\overline{\boldsymbol{R}}=$ mean number of runs
$n_{l}=$ number of outcomes of one type
$\boldsymbol{n}_{2}=$ number of outcomes of the other type
$\boldsymbol{S}_{\boldsymbol{R}}=$ standard deviation of the distribution of the number of runs.
